# CS131 Compilers: Writing Assignment 4 Due Friday, December 27, 2019 at 11:00pm

# yangyw - 2018533218

This assignment asks you to prepare written answers to questions on run-time environment, object layout, operational semantics, code generation, register allocation and garbage collection. Each of the questions has a short answer. You may discuss this assignment with other students and work on the problems together. However, your write-up should be your own individual work. and you should indicate in your submission who you worked with, if applicable. Written assignments are turned in at the start of lecture. You should use the Latex template provided at the course web site to write your solution.

I worked with: Nobody

Example for operational semantics rule in tex:

$$\frac{so, S_1, E \vdash e_1 : Bool(false), S_2}{so, S_1, E \vdash \text{while } e_1 \text{ loop } e_2 \text{ pool} : void, S_2}$$
 [Loop-False]

1. (10 pts) Consider the following Cool classes:

```
class A {
    a1 : Int;
    a2 : String;
    m1() : Object { ... };
    m2() : Object { ... };
};
class B inherits A {
    a3 : Int;
    m1() : Object { ... };
    m3() : Object { ... };
};
class C inherits B {
    a4 : Int;
    m2() : Object { ... };
    m3() : Object { ... };
};
```

(a) Draw a diagram that illustrates the layout of objects of type A, B and C, including their dispatch tables.

## Object Layout

Stack Offset  0 4 8 12 16 20 24	A tag 5 * a1 a2	B tag 6 * a1 a2 a3	C C tag 7 * a1 a2 a3 a4
		a3	

#### Dispatch Table

Stack Offset	<b>A</b>	B	$\mid \mathbf{C} \mid$
0	Object.abort	Object.abort	Object.abort
4	Object.type_name	Object.type_name	Object.type_name
8	Object.copy	Object.copy	Object.copy
12	A.m1	B.m1	A.m1
16	A.m2	A.m2	C.m2
20		B.m3	C.m3
24			
28			

(b) Let obj be a variable whose static type is A. Assume that obj is stored in register \$a0. Write MIPS code for the function invocation obj.2(). You may use temporary registers such as \$t0 if you wish.

(c) Explain what happens in part (b) if obj has dynamic type B.

When obj has the dynamic type B, the dispatch pointer of B will arrive the dispatch table of B. In that case, B will have A.m2, and will eventually reach A.m2. They have the same function inherited from A without anything wrong.

2. (10 pts) Suppose you wish to add arrays to Cool using the following syntax:

```
let a:T[e<sub>1</sub>] in e<sub>2</sub> Create an array a with size e_1 of T's, usable in e_2 a[e<sub>1</sub>] <- e<sub>2</sub> Assign e_2 to element e_1 in a Get element e of a
```

Write the operational semantics for these three syntactic constructs. You may find it helpful to think of an array of type T[n] as an object with n attributes of type T.

let  $a:T[e_1]$  in  $e_2$ 

$$so, S_{1}, E \vdash T[e_{1}] : void, S_{2}$$

$$l_{1} = newloc(S_{2})$$

$$S_{3} = S_{2}[void/l_{1}]$$

$$E' = E[l_{1}/a]$$

$$so, E', S_{3} \vdash e_{2} : void, S_{4}$$

$$so, E, S_{1} \vdash let \ a : T[e_{1}] \ in \ e_{2} : v_{2}, S_{4}$$
[Let-Array]

 $a[e_1] \leftarrow e_2$ 

$$so, E, S_1 \vdash e_2 : v, S_2$$

$$E(a[e_1]) = I_a$$

$$so, E, S \vdash a[e_1] < -e_2 : v, S$$
[Assign-Array]

a[e]

$$\begin{split} E(a[e]) &= I_a \\ S(I_a) &= v_a \\ \hline so, E, S_1 \vdash a[e] : v, S \end{split}$$
 [Reference-Array]

3. (10 pts) The operational semantics for Cool's while expression show that result of evaluating such an expression is always void. (See page 28 of the Cool manual.)

However, we could have used the following alternative semantics:

- If the loop body executes at least once, the result of the while expression is the result from the last iteration of the loop body.
- If the loop body never executes (i.e., the condition is false the first time it is evaluated), then the result of the while expression is void.

For example, consider the following expression:

while 
$$(x < 10)$$
 loop  $x <- x+1$  pool

The result of this expression would be 10 if x < 10 or void if  $x \ge 10$ .

Write new operational rules for the while construct that formalize these alternative semantics.

$$\frac{so, E, S \vdash e_1 : Bool(false), S_1}{so, E, S \vdash while \ e_1 \ loop \ e_2 \ pool : void, S_1}$$
 [Loop-False]

$$so, E, S \vdash e_1 : Bool(true), S_1$$

$$so, E, S_1 \vdash e_2 : v_1, S_2$$

$$so, E, S_2 \vdash e_1 : Bool(true), S_3$$

$$so, E, S_3 \vdash while \ e_1 \ loop \ e_2 \ pool : v_1, S_4$$

$$so, E, S \vdash while \ e_1 \ loop \ e_2 \ pool : v_1, S_4$$
[Loop-True]

$$so, E, S \vdash e_1 : Bool(true), S_1$$

$$so, E, S_1 \vdash e_2 : v_1, S_2$$

$$so, E, S_2 \vdash e_1 : Bool(false), S_3$$

$$so, E, S \vdash while \ e_1 \ loop \ e_2 \ pool : v_1, S_3$$
[Loop-Last]

4. (10 pts) Consider the following MIPS assembly code program. Using the stack-machine based code generation rules from lecture, what source program produces this code?

#### f\_entry:

```
$fp $sp
        move
               $ra 0($sp)
        SW
        addiu $sp $sp -4
        lw
               $a0 4($fp)
               $a0 0($sp)
        addiu $sp $sp -4
               $a0 0
        li
               $t1 4($sp)
        lw
        addiu $sp $sp 4
        beq
               $a0 $t1 true_branch
false_branch:
               $a0 4($fp)
        lw
               $a0 0($sp)
        addiu $sp $sp -4
               $fp 0($sp)
        addiu $sp $sp -4
```

```
lw
               $a0 4($fp)
               $a0 0($sp)
        SW
        addiu $sp $sp -4
               $a0 1
        li
        lw
               $t1 4($sp)
        sub
               $a0 $t1 $a0
        addiu $sp $sp 4
               $a0 0($sp)
        addiu $sp $sp -4
        jal
               f_entry
        lw
               $t1 4($sp)
        add
               $a0 $a0 $t1
        addiu $sp $sp 4
               end_if
        b
true_branch:
        li
               $a0 0
end_if:
        lw
               $ra 4($sp)
        addiu $sp $sp 12
        lw
               $fp 0($sp)
               $ra
        jr
Answer Here:
  def Fibonacci(x):
      if x == 0:
          return 0
      else:
          return x + Fibonacci(x-1)
```

5. (10 pts) Give a recursive definition of the cgen function for the following new construct.

```
for \mathbf{i} = \mathbf{e}_1 to \mathbf{e}_2 by \mathbf{e}_3 do \mathbf{e}_4
```

Assume that the subexpressions  $e_1, e_2, e_3$  and  $e_4$  are integer-valued. A "for loop" expression is evaluated according to the following rules. The first three subexpressions are evaluated once at the start of the loop in the order  $e_1$ ,  $e_2$ , and then  $e_3$ . The subexpression  $e_4$  is evaluated once per iteration of the loop. The index variable i is initialized to the value of  $e_1$ . The loop bound is the value of  $e_2$  and i is incremented by the value of  $e_3$  after each iteration. The loop terminates before executing an iteration where the value of i is greater than the loop bound. The value returned by the "for loop" expression is the value of the expression  $e_4$  in the last iteration. If the loop does not execute at all, then the value returned is the integer 0.

Following is a more formal semantics of the for expression in terms of the Cool expressions.

```
let t: Int \leftarrow e_1 in

let bound:Int \leftarrow e_2 in

let incr:Int \leftarrow e_3 in

let result:Int \leftarrow 0 in

let i:Int \leftarrow t in

while (i \leq \text{bound}) loop {

result \leftarrow e_4;

i \leftarrow i + \text{incr};

} pool;

result
```

Note that the expressions  $e_1$ ,  $e_2$  and  $e_3$  are evaluated ONLY once before the start of the loop. Also note that any occurrences of variable i in  $e_1$ ,  $e_2$  and  $e_3$  refer to the value of i just before the for loop. Any occurrence of variable i in expression  $e_4$  refers to the loop index variable i.

```
cgen(for i = e1 to e2 by e3 do e4) = cgen(e1)
      push($a0)
      $t0 <- top
      cgen(e_2)
      push($a0)
      $t1 <- top
      cgen(e3)
      push($a0)
      $t2 <- top
      $t3 <- 0
loop: bgt $t0 $t1 end
      cgen(e4)
      push($a0)
      $t3 <- top
      addiu $t0 $t0 $t2
      b loop
end: $a0 <- $t3
```

6. (2\*10=20 pts) Consider the following program:

```
L0: e := 0

b := 1;

d := 2;

L1: a := b+2

c := d+5

e := e + c

f := a * a

if f < c goto L3

L2: e := e + f

goto L4

L3: e := e + 2

L4: d := d + 4

b := b - 4

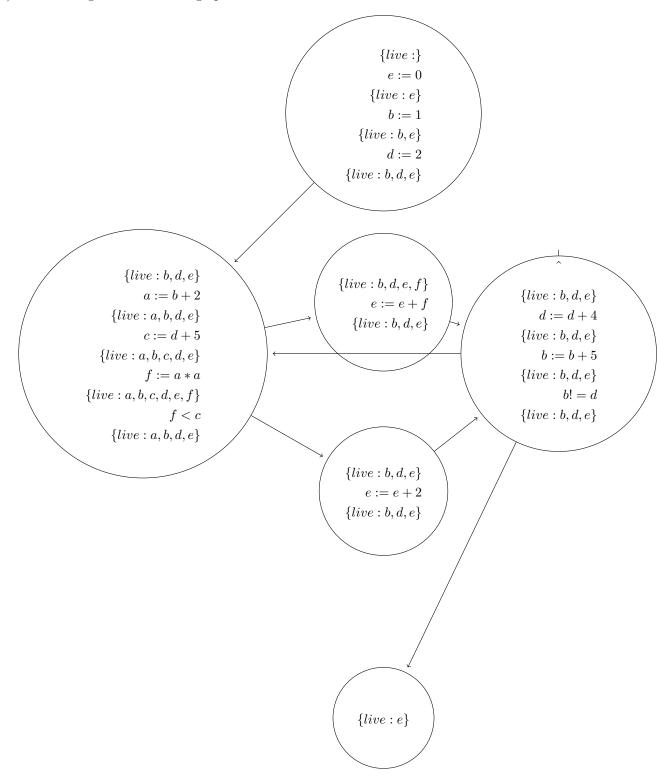

if b != d goto L1

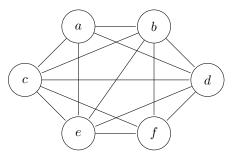

L5:
```

This program uses six temporaries a-f. Assume that our machine has only 4 available registers \$r0, \$r1, \$r2, and \$r3 and that only e is live on exit from this program.

- (a) Draw the register interference graph. (Computing the sets of live variables at every program point may be helpful for this step.)
- (b) Use the graph coloring heuristics discussed in lecture to assign each temporary to a register on a machine that has 4 registers. Rewrite the program replacing temporaries by registers and including whatever spill code is necessary. Use the pseudo-instructions load x and store x to load and spill the value of x from memory.

(a) Draw the register interference graph.

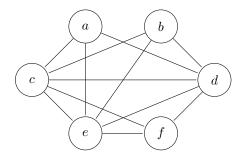

(b) assign each temporary to a register on a machine

```
LO: e := 0
    b := 1
    store b
    d := 2
L1: load b
    a := b+2
    c := d+5
    e := e + c
    f := a * a
    if f < c goto L3
L2: e := e + f
    goto L4
L3: e := e + 2
L4: d := d + 4
    load b
    b := b - 4
    store b
    if b != d goto L1
L5:
LO: r1 := 0
    r0 := 1
    store r0
    r2 := 2
L1: load r0
    r3 := r0+2
    r0 := r2+5
    r1 := r1 + r0
    r3 := r3 * r3
    if r3 < r0 goto L3
L2: r1 := r1 + r3
    goto L4
L3: r1 := r1 + 2
L4: r2 := r2 + 4
    load r0
    r0 := r0 - 4
    store r0
    if r0 != r2
       goto L1
```

L5:

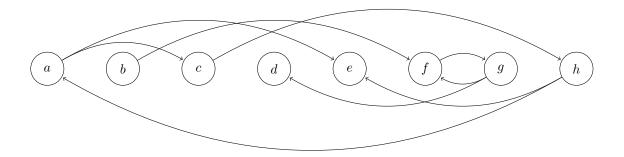

7. (10\*3=30 pts) Consider the following Cool program:

```
class C {
    x : C; y : C;
    setx(newx : C) : C { x <- newx };
    sety(newy : C) : C { y <- newy };
    setxy(newx : C, newy : C) : SELFT_TYPE {{ x <- newx; y <- newy; self; }};
};

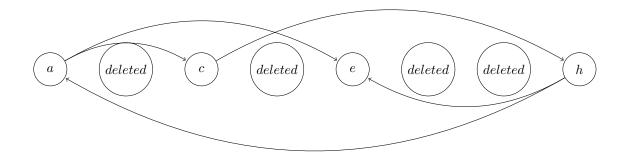

class Main {
    x:C;
    main() : Object {
      let a : C <- new C, b : C <- new C, c : C <- new C, d : C <- new C,
      e : C <- new C, f : C <- new C, g : C <- new C, h : C <- new C in {
         f.sety(g), a.setxy(e, c); b.setx(f); g.setxy(f,d); c.sety(h); h.setxy(e, a); x <- c;
    }
    };
};</pre>
```

(a) (10 pts) Draw the heap at the end of execution of the above program, identifying objects by the variable names to which they are bound in the let expression. Assume that the root is the Main object created at the start of the program, and this object is not in the heap (note that Main is pointing to c).

(b) (10 pts) For each of the garbage collection algorithms discussed in class (Mark and Sweep, Stop and Copy, Reference Counting), show the heap after garbage collection.

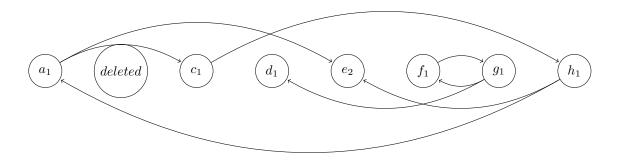

### Mark and Sweep

## Stop and Copy

### Reference Counting

- (c) (10 pts) Which technique performed the worst for the above program? Describe why the technique failed to reclaim the memory occupied by one or more heap variables which are no longer reachable. Performance is a rather vague word when used alone. We will analysis in terms of space performance and time performance.
  - As for the space occupation, reference counting is the worst. Because it even can't remove all the garbage which is not sound. The reason is beacuse any pieces of memory can't be deleted when referencing. By the rest two perform similarly.

As for the time complexity, stop and copy is the worst. It is deleting by coping the useful data to a new place and leave the useless behind. After all copy all the data verbatim is expensive than deleting.
